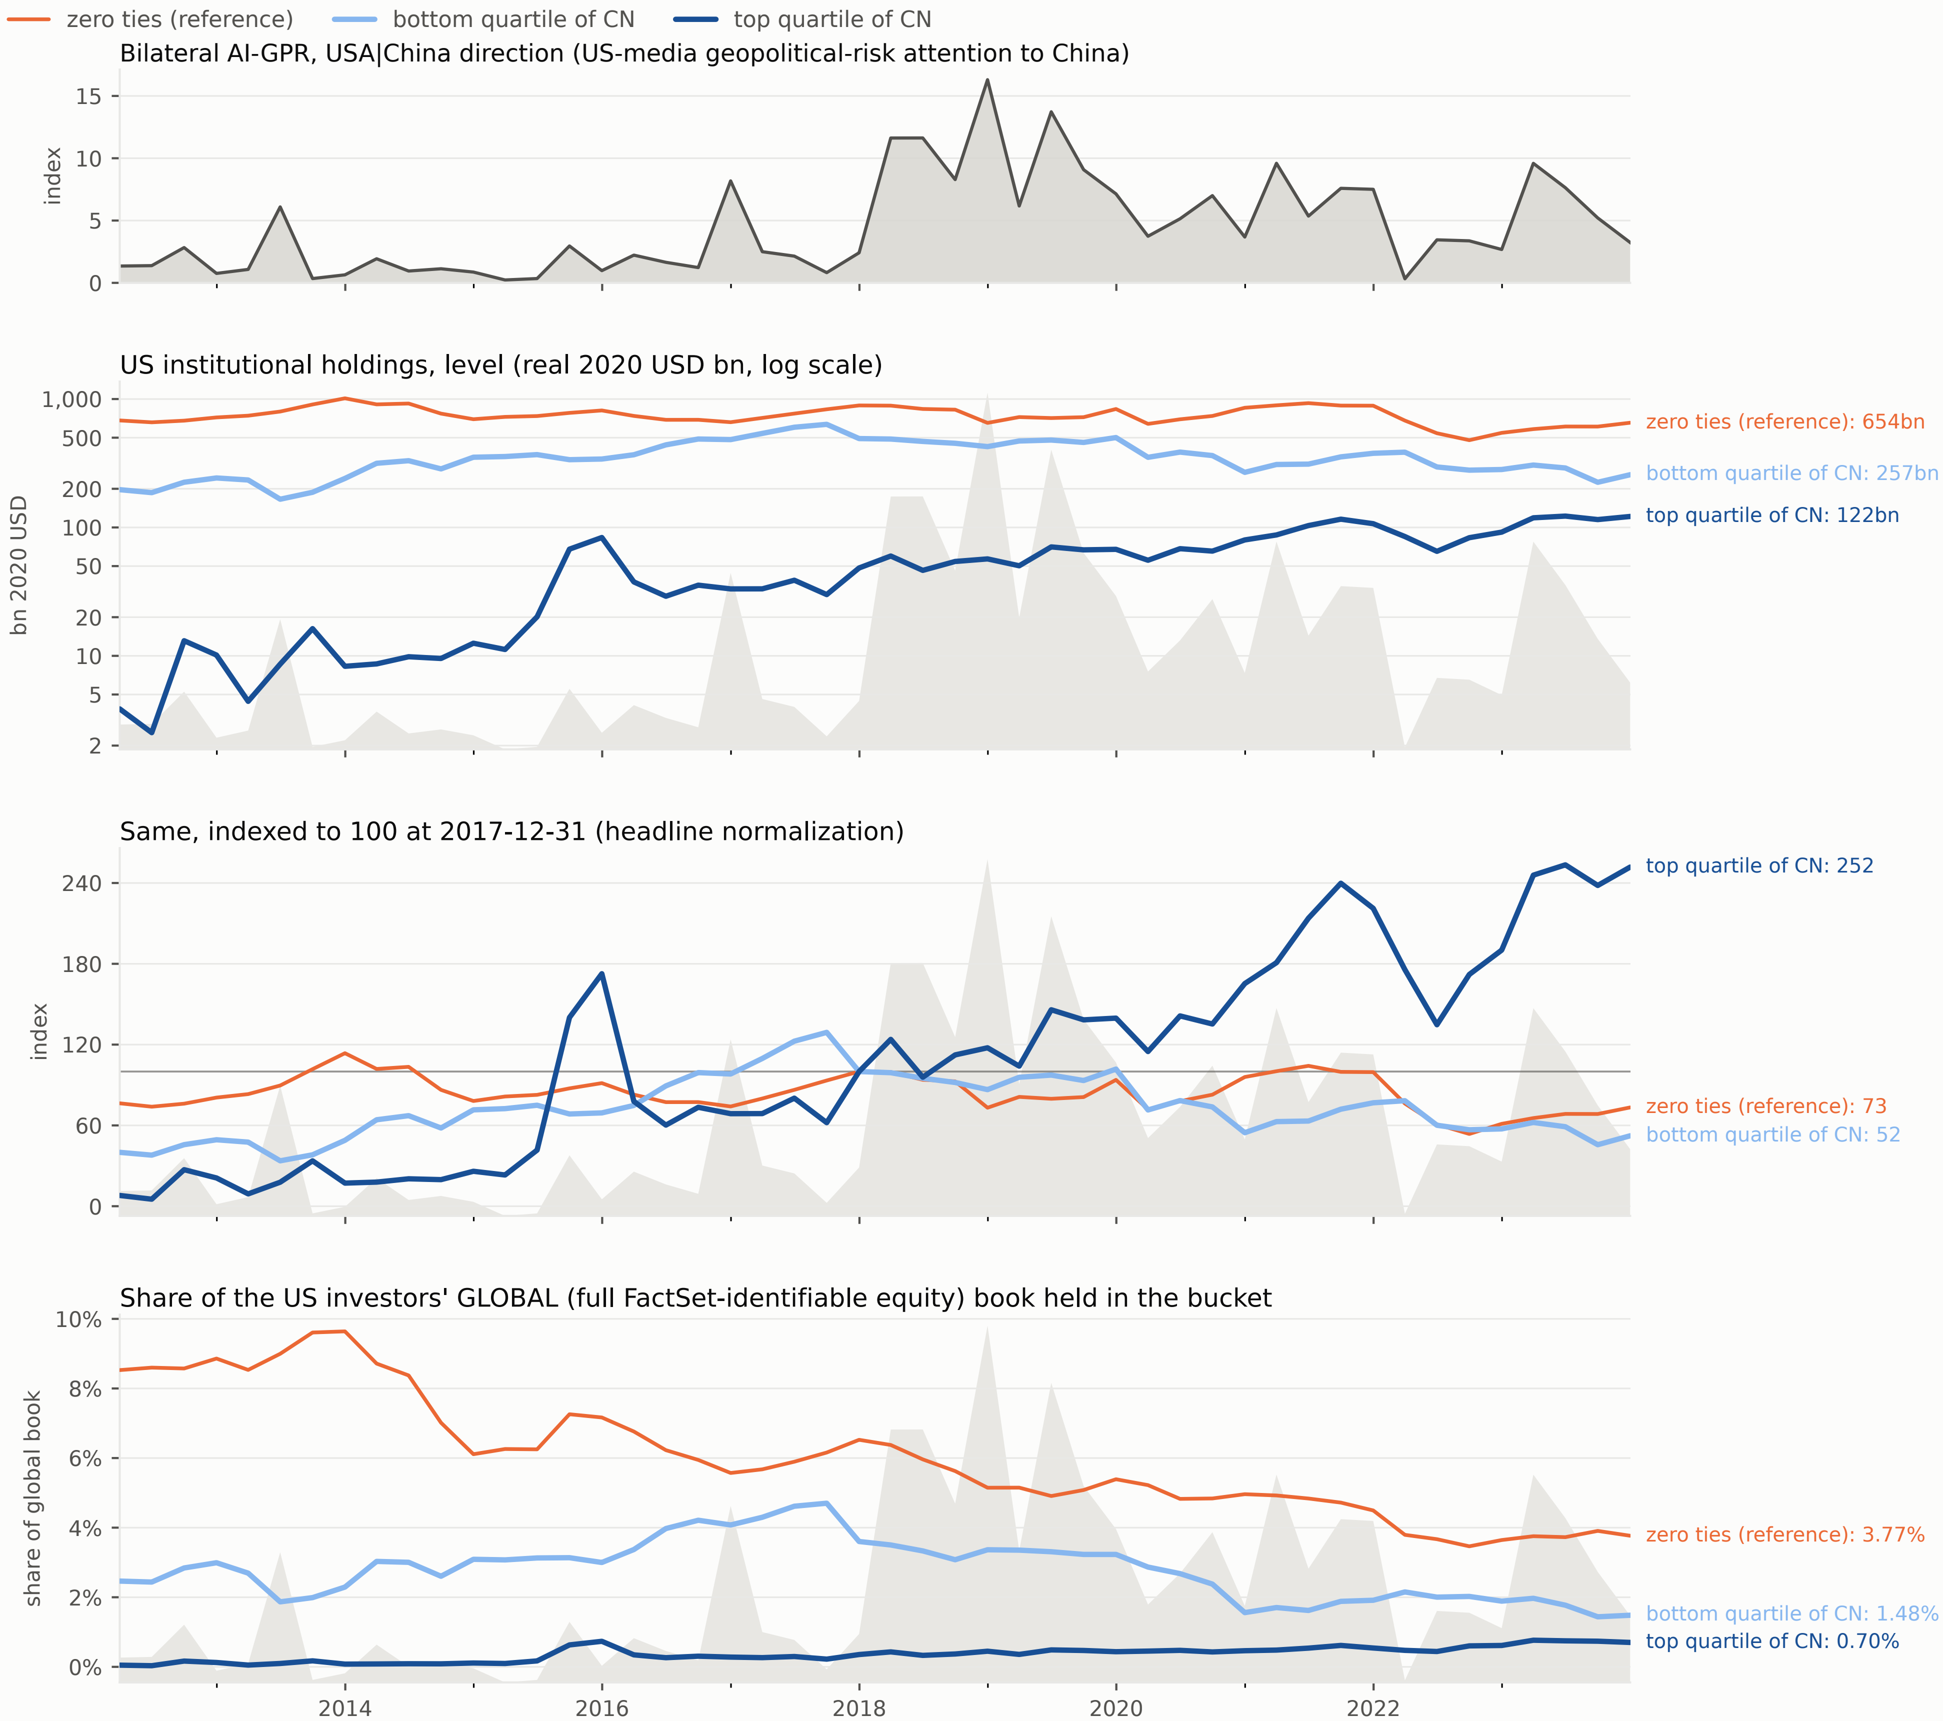
Figure A. US holdings of European firms, by China-link exposure

variant (ii), equal-weighted quartiles (M3-style)



Sample: European firms in the US/non-US ownership grid, 2012Q1-2023Q4. TIMING: buckets are assigned on the firm's China supply-chain link share CN at t-1; holdings are measured at t. CN = (China customer + China supplier links) / (all customer + supplier links); a Revere-covered firm with no supply-chain links is a genuine zero, a firm absent from Revere at t-1 is unclassified and excluded, so the buckets need not exhaust the book. Levels are CPI-U deflated (CPIAUCNS, quarter-end month, 2020 annual-average base) exactly as in the Figure-2 builder. The share panel uses the GLOBAL (full FactSet-identifiable equity) denominator, the same denominator as the main regression; the EU-book version of the series (share_of_book_eu in fig_A_firm_buckets.csv) is the within-Europe reallocation diagnostic and is not plotted. Background silhouette in the three lower panels = Bilateral AI-GPR, USA|China direction (US-media geopolitical-risk attention to China), scaled to panel height with no axis and no ticks; read its level off the top panel. Quartile cutpoints are the unweighted 25/50/75th percentiles of CN among positive-CN firms that quarter (M3-style, one firm one vote); assignment is by value, so tied ratios never straddle a boundary. Q2 and Q3 are in the CSV but omitted here to keep three lines per panel. The zero bucket is drawn as its own recessive line rather than folded into Q1: after the zero recode it mixes firms with a supply-chain denominator and no China link with firms that have no supply-chain links at all, so it is not the low tail of the same distribution.
