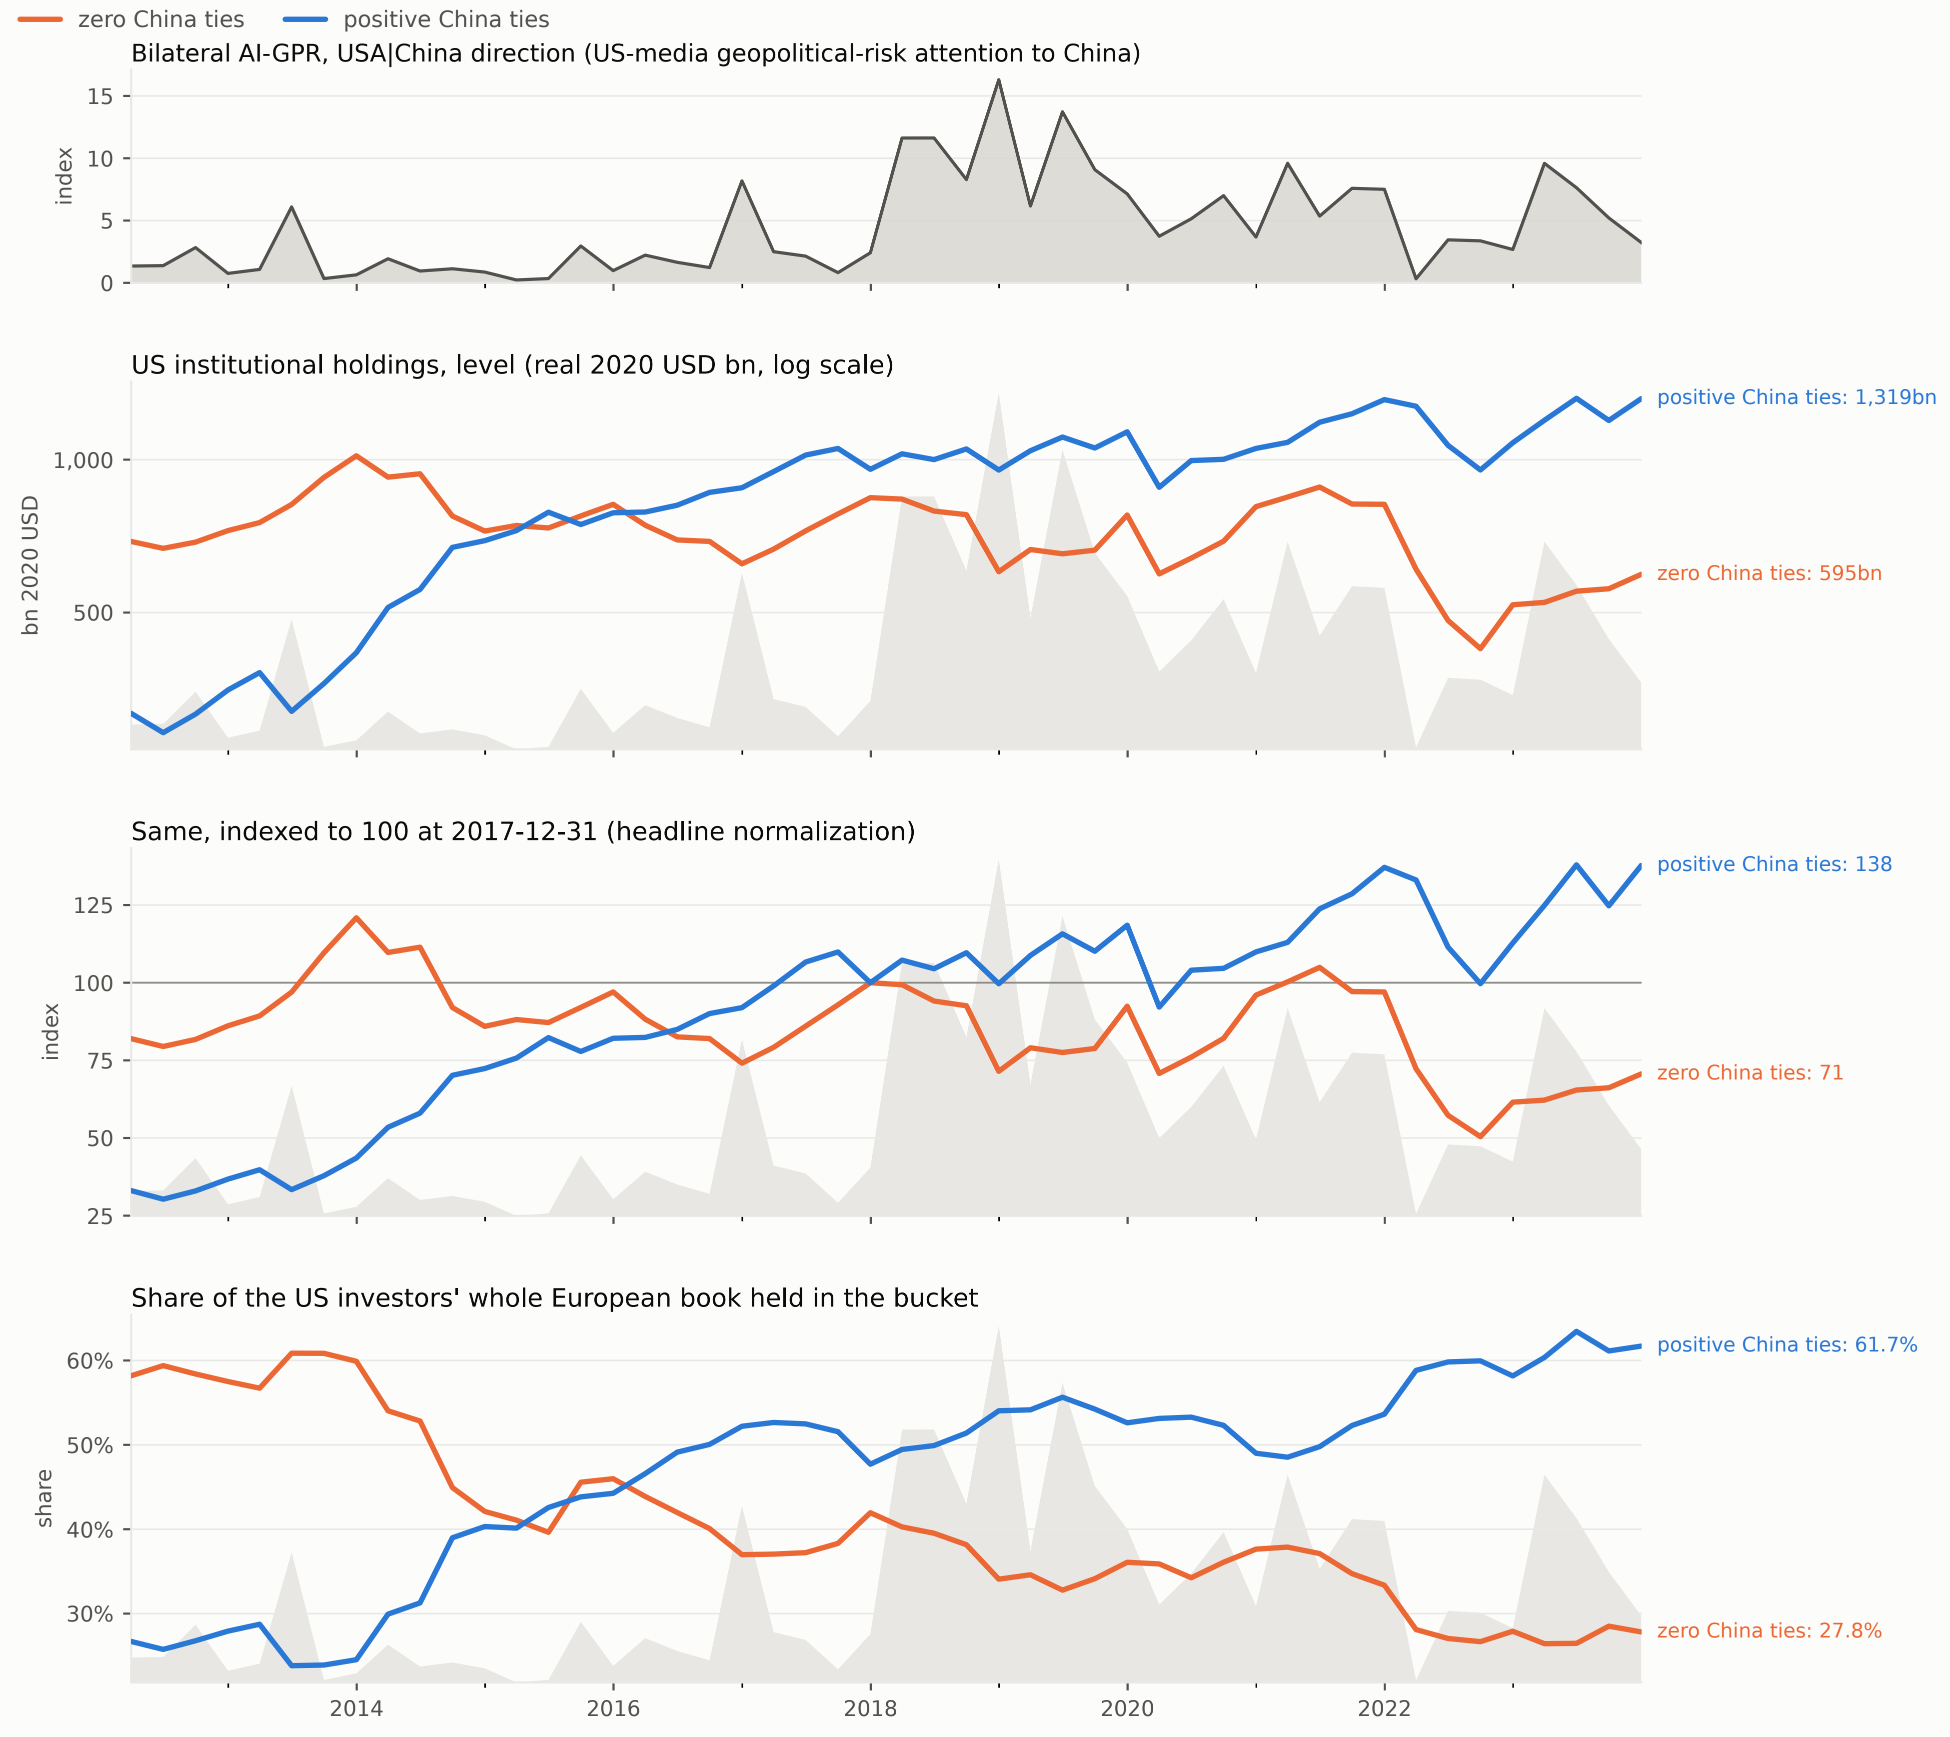
Figure A. US holdings of European firms, by China-link exposure

variant (i), zero vs positive ties



Sample: European firms in the US/non-US ownership grid, 2012Q1-2023Q4. TIMING: buckets are assigned on the firm's China supply-chain link share CN at t-1; holdings are measured at t. CN = (China customer + China supplier links) / (all customer + supplier links); a Revere-covered firm with no supply-chain links is a genuine zero, a firm absent from Revere at t-1 is unclassified and excluded, so the buckets need not exhaust the book. Levels are CPI-U deflated (CPIAUCNS, quarter-end month, 2020 annual-average base) exactly as in the Figure-2 builder. Background silhouette in the three lower panels = Bilateral AI-GPR, USA|China direction (US-media geopolitical-risk attention to China), scaled to panel height with no axis and no ticks; read its level off the top panel.
Both arms are Revere-covered at t-1; the zero arm is a measured zero, not a missing value. CAVEAT, and the reason the companion figure exists: with the rolling t-1 rule the positive arm grows from 144 firms in 2012Q1 to 766 in 2023Q1 because Revere keeps adding relationships, so part of the rise in its share of the book is RECLASSIFICATION, not reallocation.
fig_A_firm_zero_vs_positive_fixedcohort freezes bucket membership at 2017Q4 and isolates the reallocation component.
