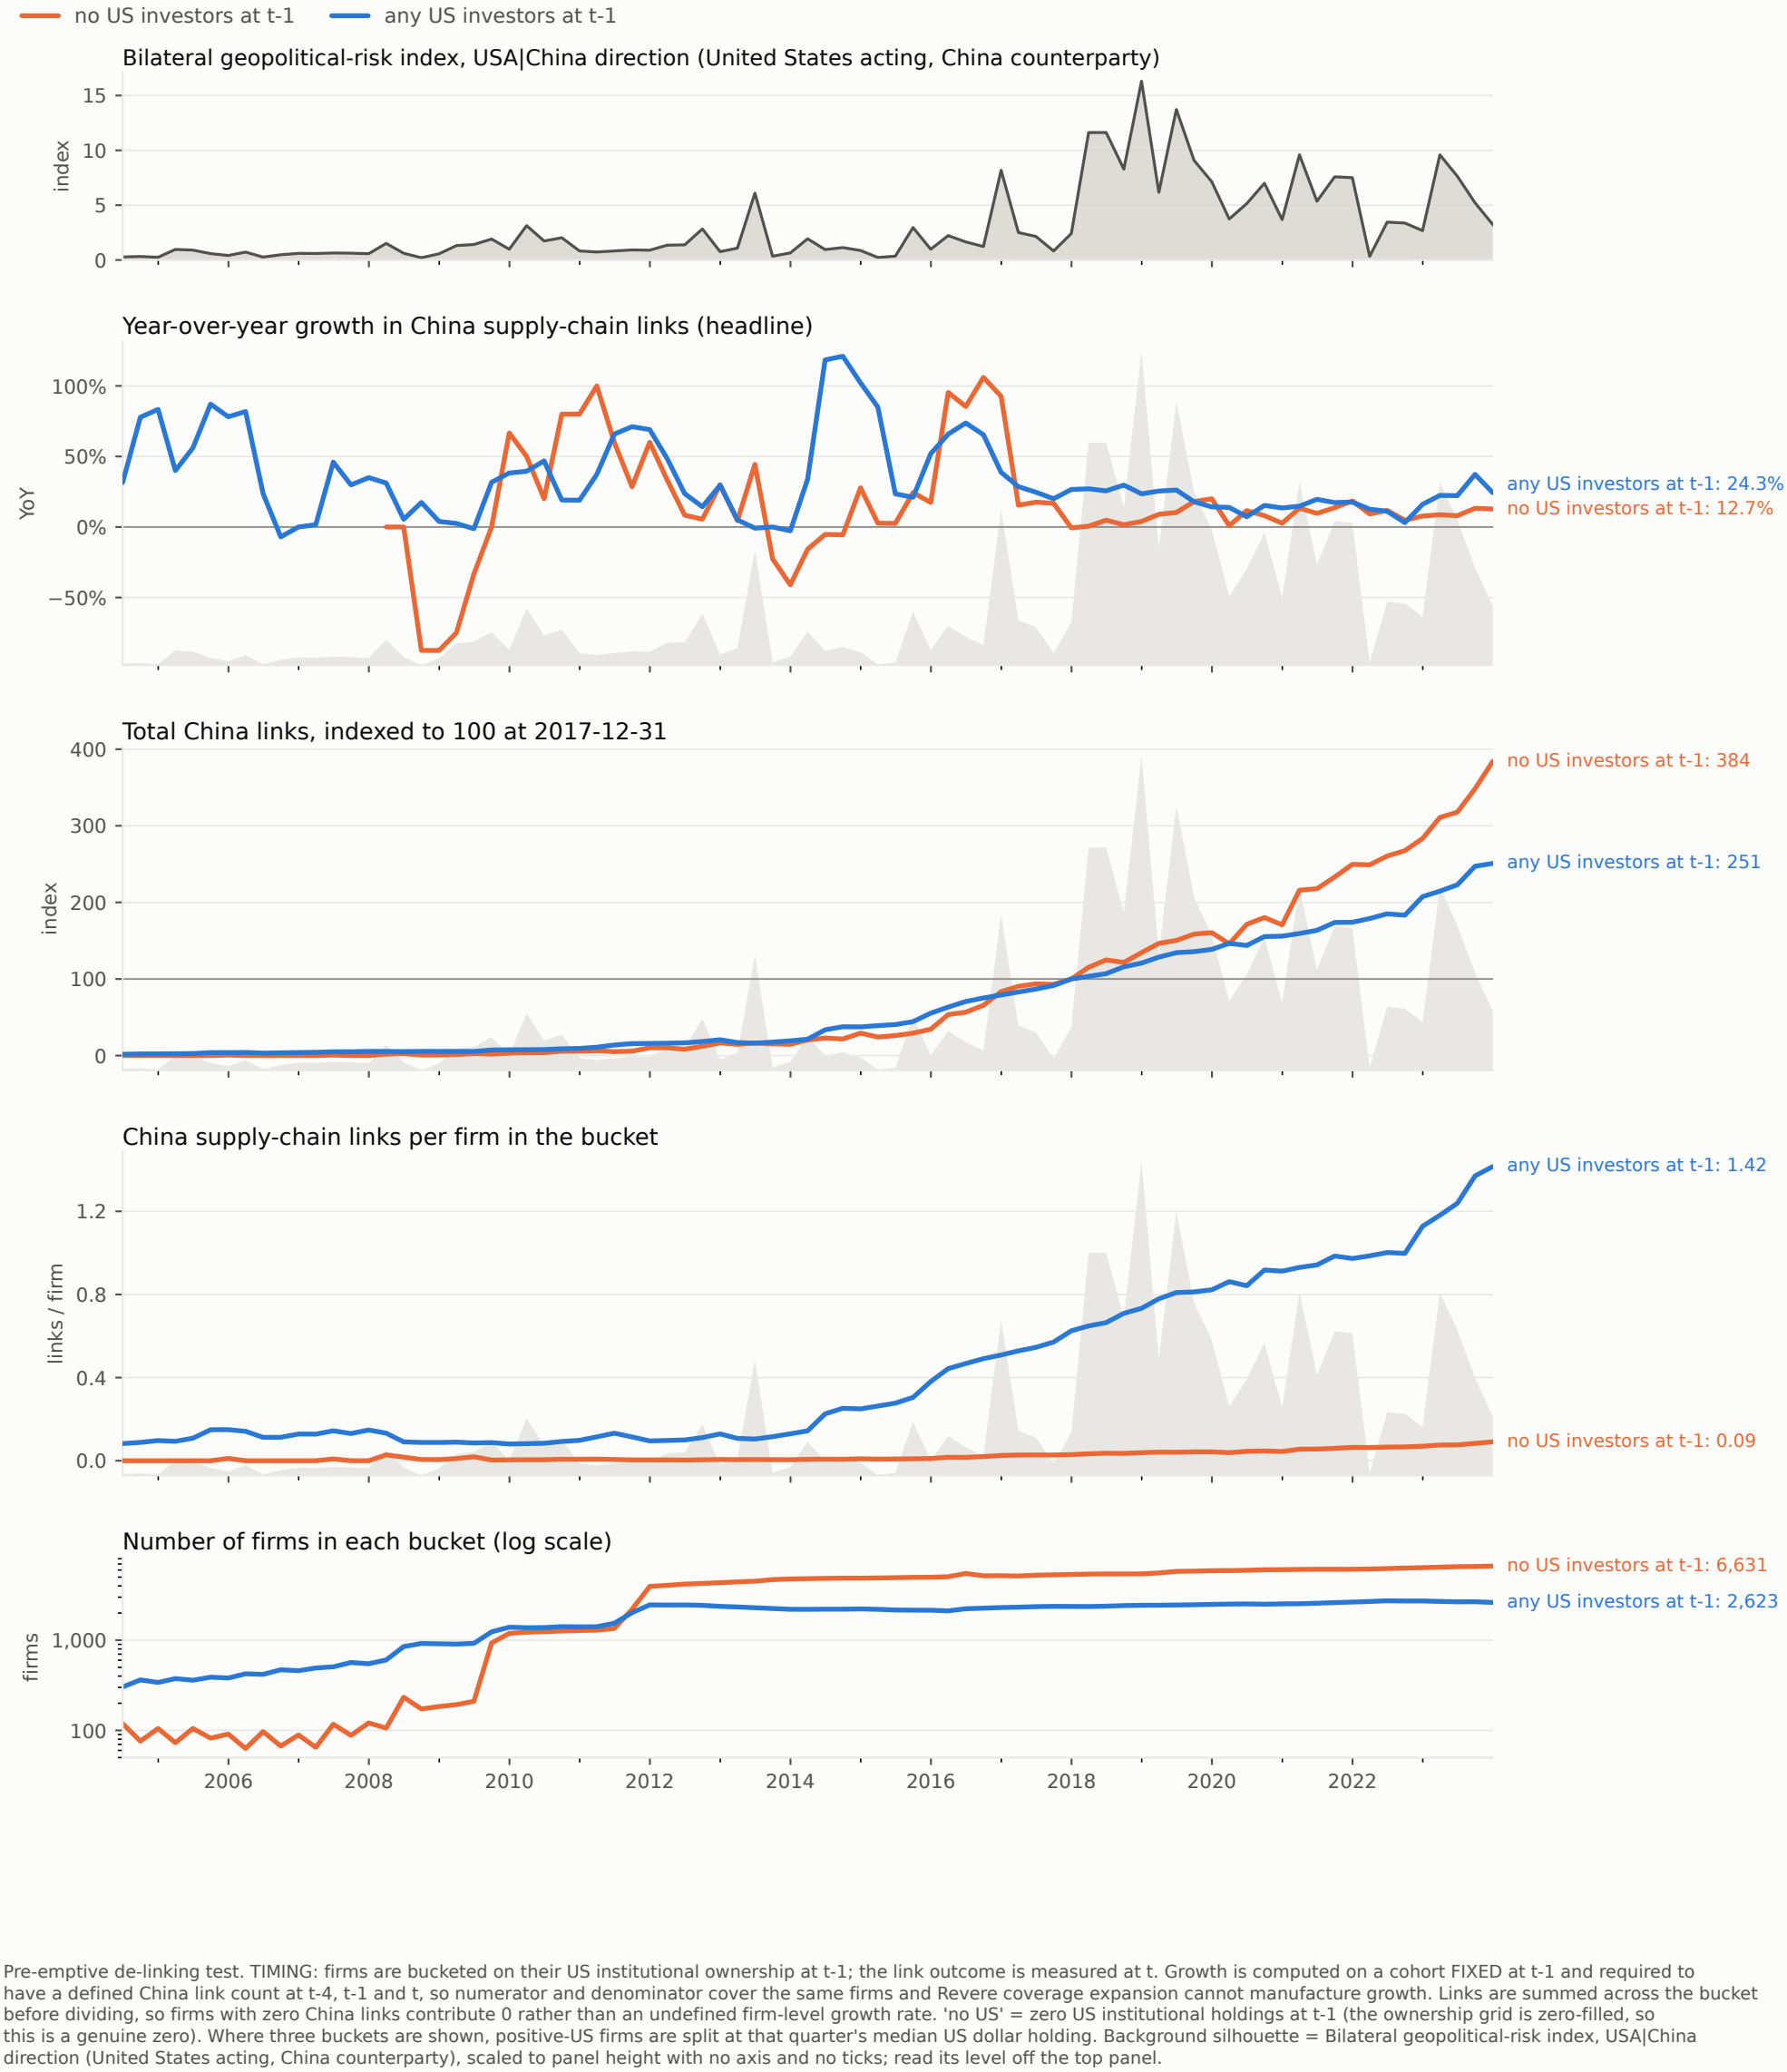
Figure B. China supply-chain link growth, by US ownership at t-1

two buckets



Pre-emptive de-linking test. TIMING: firms are bucketed on their US institutional ownership at t-1; the link outcome is measured at t. Growth is computed on a cohort FIXED at t-1 and required to have a defined China link count at t-4, t-1 and t, so numerator and denominator cover the same firms and Revere coverage expansion cannot manufacture growth. Links are summed across the bucket before dividing, so firms with zero China links contribute 0 rather than an undefined firm-level growth rate. 'no US' = zero US institutional holdings at t-1 (the ownership grid is zero-filled, so this is a genuine zero). Where three buckets are shown, positive-US firms are split at that quarter's median US dollar holding. Background silhouette = Bilateral geopolitical-risk index, USA|China direction (United States acting, China counterparty), scaled to panel height with no axis and no ticks; read its level off the top panel.
